RESULTS OF THE EXPERIMENTAL STUDY  
ON THE EFFECTS OF VIBRATION ON  
HUMAN PERFORMANCE

The purpose of this study was to determine the effects of vibration on human performance. The study was conducted in a laboratory setting and involved a number of subjects who were exposed to different levels of vibration. The results of the study are presented in the following sections.

The first section of the study was a pre-test in which the subjects were familiarized with the equipment and the procedures. The second section was the main experiment in which the subjects were exposed to three different levels of vibration: low, medium, and high. The subjects were then asked to perform a series of tasks, including a simple reaction time test, a complex task, and a task requiring fine motor control.

The results of the study showed that vibration had a significant effect on human performance. The subjects who were exposed to high vibration performed significantly worse on all three tasks compared to the subjects who were exposed to low or medium vibration. The subjects who were exposed to medium vibration performed significantly worse on the complex task and the task requiring fine motor control compared to the subjects who were exposed to low vibration.

The results of the study also showed that the effects of vibration on human performance were more pronounced in the subjects who were exposed to high vibration for a longer duration. This suggests that the effects of vibration on human performance are cumulative and that the longer the subjects are exposed to high vibration, the more their performance is affected.

The results of the study have important implications for the design of work environments. It is important to minimize the effects of vibration on human performance in order to ensure the safety and health of workers. This can be achieved by using vibration-dampening equipment, such as anti-vibration mats and chairs, and by limiting the duration of exposure to high vibration.
